# BRO CHEAT SHEET

Version: November 29, 2011

Website: http://www.bro-ids.org

Download: https://github.com/broids/cheat-sheet

License: Attribution-NonCommercial-ShareAlike 3.0 Unported

## Startup

bro [options] [file]
fileBro policy script or stdin
-e codeAugment policies by given code
-h Display command line options
-i iface Read from given interface
-p pfxAdd given prefix to policy resolution
-r fileRead from given PCAP file
-w file Write to given file in PCAP format
-x file Print contents of state file
-CIgnore invalid checksum

## Language

Lowercase letters represent instance variables and uppercase letters represent types. In general, x is an instance of type T and y an instance of type U. Argument names and record fields begin with a, b, ..., and  ${f z}$  represents a default instance variable which takes on the type of the right-hand side expression. For notational convenience, x can often be replaced with an expression of type T.

## Variables

Constant qualifiercor	ıst
Constant redefinitionredef x op ex	pr
Scope qualifierlocal, glob	al
Declarationscope x:	T
Declaration & Definitionscope $z = ex$	pr

## **Declarations**

Type type	name:	T
Function function f(a: T,	):	R
Eventevent e(a:	Τ,	.)

## Modules

### **Statements**

Basic statementstmt; or expr;
Code block { $stmt$ ; }
Assignment $z = expr$
Function assignmentz = function(): R {}
Event queuing event e()
Event schedulingschedule 10 secs { e() }
Print expression to stdoutprint expr

!	Branching	ITERATION	CONTROL	Decla
	if ( <i>expr</i> ) { }	for (i in x) { }	break continue	Const Assign Acces
	else if $(expr)$ $\{ \dots \}$	Asynchronous	next return	Field Deleti
	else { }	when (expr) { when (local x =	} = expr) { }	

## Expressions

OPERATORS

!
\$, ?\$ Dereference, record field existence
+, -, *, /, %Arithmetic
++,
+=, $-=$ , $*=$ , $/=$ Arithmetic and assignment
==, != Equality, inequality
<, $<=$ , $>=$ , $>$ Less/greater than (or equal)
&&,     Conjunction, disjunction
in, !inMembership or pattern matching
[x] Index strings and containers
x  Cardinality/size for strings and containers
f()Function call
expr ? expr : expr

## **Types**

Basic	
addr IP a	ddress (127.0.0.1)

bool
ENUMERABLES

## Declaration ..... enum { FOO, BAR } Assignment .....scope x = F00

Records
Declaration record { a: T, b: U, }
Constructorrecord(\$a=x, \$b=y,)
Assignmentscope $r = [\$a=x, \$b=y,]$
Accessz = r\$a
Field assignmentr\$b = y
Deletiondelete r\$a

Declaration set[T]
Constructor set(x,)
Assignmentscope $s = \{ x, \dots \}$
Access $z = s[x]$
Insertionadd s[x]
Deletiondelete s[x]

Tables
Declarationtable[T] of U
Constructor table([x] = y,)
Assignmentscope $t = \{ [x] = y, \}$
Access $z = t[x]$
Insertiont[x] = y
Deletiondelete t[x]

### Attributes

Attributes occur at the end of type/event declarations and change their behavior. The syntax is &key or &key=val, e.g., type T: set[count] &read\_expire=5min or event foo() &priority=-3.

 &optional
 Allow record field to be missing

 &default=x
 Use default value x for record fields and container elements

 &redef
 Allow for redefinition of initial object value

 &expire\_func=f
 Call f right before container element expires

 &read\_expire=x
 Remove element after not reading it for time x

 &write\_expire=x
 Remove element after into writing it for time x

 &create\_expire=x
 Remove element after time x from insertion

 &persistent
 Write state to disk (per default on shutdown)

 &synchronized
 Synchronize variable across nodes

 &raw\_output
 Do not escape non-ASCII characters when writing to a file

 &mergeable
 Prefer set union to assignment for synchronized state

 &priority=x
 Execution priority of event handler, higher values first, default 0

 &group="x"
 Events in the same group can be jointly activated/deactivated

 &log
 Write record field to log

## **Built-In Functions (BIFs)**

#### Core

- getenv(var: string): string
   Returns the system environment variable identified by var, or an empty string
   strftime(fmt: string, d: time): string
   Formats the time value d according to the form
- setenv(var: string, val: string): bool Sets the system environment variable var to val.
- syslog(s: string)
  Send the string s to syslog.
- system(s: string): int

Invokes a command via the system function. Returns true if the return value of system was non-zero. Returns the return value from the system() call. Note that this corresponds to the status of backgrounding the given command, not to the exit status of the command itself. A value of 127 corresponds to a failure to execute sh, and -1 to an internal system failure. Furthermore, the command is run in the background with stdout redirected to stderr. Here is a usage example: system(fmt("rm \"%s\"", str\_shell\_escape(sniffed\_data)));

- piped\_exec(program: string, to\_write: string): bool
  Opens the application program with popen and writes the string to\_write to
  stdin of the opened program.
  the function returns a MIME type string
  unique\_id(prefix: string): string
  Creates an identifier that is unique with he
- srand(seed: count)

Set the seed for subsequent rand calls.

- rand(max: count): count
  Returns a random value from the interval [0, max).
- md5\_hash(...): string
  Computes the MD5 hash value of the provided list of arguments.
- md5\_hash\_init(index: any): bool
  Initializes MD5 state for index to allow for computing hash values incrementally via the function md5\_hash\_update. For example, when computing incremental MD5 values of transferred files in multiple concurrent HTTP connections, it is necessary to call md5\_hash\_init(c\$id) once before invoking md5\_hash\_update(c\$id, some\_more\_data) in the http\_entity\_data event handler.
- function md5\_hash\_update(index: any, data: string): bool Update the MD5 value associated with index. Note that it is necessary to call md5\_hash\_init(index) once before calling this function to initialize the MD5 state.
- md5\_hash\_finish(index: any): string
  Returns the final MD5 digest associated with the internal state identified by
  index.
- md5\_hmac(...): string Computes an HMAC-MD5 hash value of the provided list of arguments. The HMAC secret key is generated from available entropy when Bro starts up, or it can be specified for repeatability using the -K flag.
- file\_size(f: string): double
  Returns the file size in bytes of the file identified by f.
- strftime(fmt: string, d: time): string
  Formats the time value d according to the format string fmt. See man strftime
  for the format of fmt.
- lookup\_addr(host: addr): string
  Issues an asynchronous reverse DNS lookup and delays the function result. Therefore, it can only be called inside a when-condition, e.g., when (local host = lookup\_addr(10.0.0.1)) { f(host); }. Returns the DNS name of host.
- lookup\_hostname(host: string): set[addr]
  Issues an asynchronous DNS lookup and delays the function result. Returns a set containing the addresses that host resolves to. See lookup\_addr for a usage example.
- identify\_data(data: string, return\_mime: bool): string
  Invokes libmagic on data to determine its MIME type. If return\_mime is true,
  the function returns a MIME type string instead of a textual description.
- unique\_id(prefix: string): string

  Creates an identifier that is unique with high probability, with prefix prepended
  to the result.

- unique\_id\_from(pool: int, prefix: string): string

  Same as unique\_id, except that the additional argument pool specifies a seed for determinism.
- terminate(): bool Gracefully shut down Bro by terminating outstanding processing. Returns true after successful termination and false when Bro is still in the process of shutting down.
- exit() Shuts down the Bro process immediately.

#### Introspection

- bro\_version(): string Returns the Bro version string.
- getpid(): count Returns Bro's process ID.
- do\_profiling()

Enable detailed collections of statistics about CPU/memory usage, connections, TCP states/reassembler, DNS lookups, timers, and script-level state. The script variable profiling\_file holds the name of the log file.

- gethostname(): string
  Get the value of the hostname of the machine Bro runs on.
- current\_time(): time Returns the current wall-clock time.
- network\_time(): time

Returns the timestamp of the last packet processed. Returns the timestamp of the most recently read packet, whether read from a live network interface or from a save file. Compare against current\_time. In general, you should use network\_time unless you're using Bro for non-networking uses (such as general scripting; not particularly recommended), because otherwise your script may behave very differently on live traffic versus played-back traffic from a save file.

- net\_stats(): NetStats
  Returns statistics about the number of packets (i) received by Bro, (ii) dropped, and (iii) seen on the link (not always available).
- resource\_usage(): bro\_resources
  Returns Bro process statistics, such as real/user/sys CPU time, memory usage, page faults, number of TCP/UDP/ICMP connections, timers, and events queued/dispatched.
- get\_matcher\_stats(): matcher\_stats
  Returns statistics about the regular expression engine, such as the number of
  distinct matchers, DFA states, DFA state transitions, memory usage of DFA
  states, cache hits/misses, and average number of NFA states across all matchers.
- dump\_rule\_stats(f: file): bool
  Write rule matcher statistics (DFA states, transitions, memory usage, cache

hits/misses) to the file f. Returns true on success.

- get\_gap\_summary(): gap\_info Returns statistics about TCP gaps.
- is\_local\_interface(ip: addr): bool
  Returns true if the address ip is a valid DNS entry for localhost.

### **Analyzer Behavior**

- skip\_further\_processing(id: conn\_id): bool
  Informs Bro that it should skip any further processing of the contents of the connection identified by id. In particular, Bro will refrain from reassembling the TCP byte stream and from generating events relating to any analyzers that have been processing the connection. Bro will still generate connection-oriented events such as connection\_finished. Returns false if id does not point to an active connection and true otherwise. Note that this does not in itself imply that packets from this connection will not be recorded, which is controlled separately by set\_record\_packets.
- set\_record\_packets(id: conn\_id, do\_record: bool): bool
  Controls whether packet contents belonging to the connection identified by id
  should be recorded (when -w out.pcap is provided on the command line). Note
  that this is independent of whether Bro processes the packets of this connection,
  which is controlled separately by skip\_further\_processing.
- set\_contents\_file(id: conn\_id, direction: count, f: file): bool
  Associates the file handle f with the connection identified by id for writing
  TCP byte stream contents. The argument direction controls what sides of the
  connection contents are recorded; it can take on four values:
- CONTENTS\_NONE: Stop recording the connection's content.
- CONTENTS\_ORIG: Record the data sent by the connection originator (often the client).
- CONTENTS\_RESP: Record the data sent by the connection responder (often the server).
- CONTENTS\_BOTH: Record the data sent in both directions. Results in the two directions being intermixed in the file, in the order the data was seen by Bro. Returns false if id does not point to an active connection and true otherwise. Note that the data recorded to the file reflects the byte stream, not the contents of individual packets. Reordering and duplicates are removed. If any data is missing, the recording stops at the missing data; this can happen, e.g., due to an ack\_above\_hole event.
- get\_contents\_file(id: conn\_id, direction: count): file
  Returns the file handle associated with the connection identified by id and
  direction. If the connection exists but no contents file for direction, the
  function returns a handle to new file. If not active connection for id exists, it
  returns an error.

- skip\_http\_entity\_data(c: connection, is\_orig: bool) Skips the data of the HTTP entity in the connection c. If is\_orig is true, the • enable\_raw\_output(f: file) client data is skipped and the server data otherwise.
- skip\_smtp\_data(c: connection) Skips SMTP data until the next email in c.
- dump\_current\_packet(file\_name: string): bool Writes the current packet to the file identified by file\_name. Returns true on success.
- get\_current\_packet(): pcap\_packet Returns the currently processed PCAP packet, which is a record containing a timestamp, the "snaplen," and the packet data.
- dump\_packet(pkt: pcap\_packet, file\_name: string): bool Writes the packet pkt to the file identified by file\_name. Returns true on success.
- set\_inactivity\_timeout(id: conn\_id, t: interval): interval Sets an individual inactivity timeout for the connection identified by id (overrides the global inactivity timeout). Returns the previous timeout interval.

#### Files and Directories

- open(f: string): file Opens the file identified by f for writing. Returns a handle for subsequent file operations.
- open\_for\_append(f: string): file Same as open, except that f is not overwritten and content is appended at the end of the file.
- close(f: file): bool Closes the file handle f and flushes buffered content. Returns true on success.
- active\_file(f: file): bool Checks whether f is open.
- write\_file(f: file, data: string): bool Writes data to f. Returns true on success.
- get\_file\_name(f: file): string Returns the filename associated with f.
- set\_buf(f: file, buffered: bool) Alters the buffering behavior of f. When buffered is true, the file is fully buffered, i.e., bytes are saved in a buffered until the block size has been reached. When buffered is false, the file is line buffered, i.e., bytes are saved up until a newline occurs.
- flush all(): bool Flushes all open files to disk. Returns true when the operations(s) succeeded.
- mkdir(f: string): bool Creates a new directory identified by f. Returns true if the operation succeeds

and f does not exist already.

Function equivalent to the &raw\_output attribute, which prevents escaping of non-ASCII characters when writing to f.

#### Generic Programming

- length(v: any): count Returns the number of elements in the container v.
- val\_size(v: any): count Returns the number bytes that v occupies in memory.
- clear\_table(v: any) Removes all elements from the set or table v.
- resize(v: any, newsize: count): count. Resizes the vector v to the size newsize. Returns the old size of v and 0 if v is not a vector type.
- any\_set(v: any): bool Test whether the boolean vector (vector of bool) has any true element, i.e., checks whether  $\exists x \in \mathbf{v} : x = \mathbf{T}$ .
- all\_set(v: any): bool Test whether all elements of the boolean vector (vector of bool) are true, i.e., checks whether  $\forall x \in v : x = T$ . Missing elements count as false.
- sort(v: any, ...): any Sorts the vector v in place and returns the original vector. The second argument is a comparison function that takes two arguments: if the type of v is vector of T, then the comparison function is function(a: T, b: T): bool that returns a < b for some type-specific notion of the less-than operator.
- order(v: any, ...): vector of count Returns the order of the elements in the vector v according to some comparison function. See sort.

#### Math

- floor(x: double): double Chops off any decimal digits of x, i.e., computes |x|.
- sqrt(x: double): double Returns the square root of x, i.e., computes  $\sqrt{x}$ .
- exp(x: double): double Raises e to the power of x, i.e., computes  $e^{x}$ .
- ln(x: double): double Returns the natural logarithm of x, i.e., computes ln x.
- log10(x: double): double Returns the common logarithm of x, i.e., computes  $\log_{10} x$ .

#### String Processing

- byte\_len(s: string): count Returns the number of characters (i.e., bytes) in s. This includes any embedded • gsub(s: string, re: pattern, repl: string): string NULs, and also a trailing NUL, if any (which is why the function isn't called strlen: to remind the user that Bro strings can include NULs).
- sub\_bytes(s: string, start: count, n: int): string Extracts a substring of s, starting at position start and having length n.
- split(s: string, re: pattern): table[count] of string Splits s into an array using re to separate the elements. The returned table starts at index 1. Note that conceptually the return value is meant to be a vector and this might change in the future.
- split1(s: string, re: pattern): table[count] of string Same as split, but s is only split once (if possible) at the earliest position and an array of two strings is returned. An array of one string is returned when s • to\_lower(s: string): string cannot be split.
- split\_all(s: string, re: pattern): table[count] of string Same as split, but also include the matching separators, e.g., • to\_upper(s: string): string split\_all("a-b--cd", /(\-)+/) returns {"a", "-", "b", "--", "cd"}. Odd-indexed elements do not match the pattern and even-indexed ones do.
- split\_n(s: string, re: pattern, incl\_sep: bool, max\_num\_sep: count): table[count] of string Similar to split1 and split\_all, but incl\_sep indicates whether to include matching separators and max\_num\_sep the number of times to split s.
- str\_split(s: string, idx: vector of count): vector of string Splits s into substrings, taking all the indices in idx as cutting points; idx does not need to be sorted and out-of-bounds indices are ignored.
- string\_cat(...): string Concatenes a variable number of string arguments into a single string.
- cat\_string\_array(a: table[count] of string): string Same as string\_cat, except that it takes an array of strings as argument and concatenates its values into a single string.
- cat\_string\_array\_n(a: table[count] of string, start: count, end: count): string Same as cat\_string\_array, but only concatenates the strings from index start to end.
- join\_string\_array(sep: string, a: table[count] of string): string Concatenates all elements in a into a single string, with sep placed between each element.
- join\_string\_vec(v: vector of string, sep: string): string Concatenates all elements in v into a single string, with sep placed between each element.
- sort\_string\_array(a: table[count] of string): string

- Sorts the string array a and returns a sorted copy.
- sub(s: string, re: pattern, repl: string): string Substitutes repl for the first occurrence of re in s.
- Same as sub except that all occurrences of re are replaced.
- strcmp(s1: string, s2: string): int Lexicographically compares s1 and s2. Returns an integer greater than, equal to, or less than 0 according as s1 is greater than, equal to, or less than s2.
- strstr(big: string, little: string): count Locates the first occurrence of little in big. Returns 0 if little is not found in big.
- subst\_string(s: string, from: string, to: string): string Substitutes each (non-overlapping) appearance of from in s to to, and return the resulting string.
- Returns a copy of the given string with the uppercase letters (as indicated by isascii and isupper) folded to lowercase (via tolower).
- Returns a copy of s with the lowercase letters (as indicated by isascii and islower) folded to lowercase (via toupper).
- is\_ascii(s: string): bool Returns false if any byte value of s is greater than 127, and true otherwise.
- edit(s: string, edit\_char: string): string Returns a version of s assuming that edit\_char is the "backspace character" (usually \x08 for backspace or \x7f for DEL). For example, edit("hello there", "e") returns "llo t". The argument edit\_char must be a string of exactly one character, or Bro generates a run-time error and uses the first character in the string.
- clean(s: string): string Replaces non-printable characters in s with escaped sequences, with the mappings NUL  $\rightarrow$  \0, DEL  $\rightarrow$  ^?, values < 26  $\rightarrow$  ^[A-Z], and values not in  $[32, 126] \rightarrow \%XX$ . If the string does not yet have a trailing NUL, one is added.
- to\_string\_literal(s: string): string Same as clean, but with different mappings: values not in  $[32,126] \rightarrow \%XX$ ,  $\backslash \rightarrow \backslash \backslash$ ,  $\prime \rightarrow \backslash \prime$ , "  $\rightarrow \backslash$ ".
- escape\_string(s: string): string Returns a printable version of s. Same as clean except that non-printable characters are removed.
- string\_to\_ascii\_hex(s: string): string Returns an ASCII hexadecimal representation of a string.
- strip(s: string): string Strips whitespace at both ends of s.

- string\_fill(len: int, source: string): string
  Generates a string of size len and fills it with repetitions of source.
- str\_shell\_escape(source: string): string
  Takes a string and escapes characters that would allow execution of commands
  at the shell level. Must be used before including strings in system or similar
  calls.
- find\_all(s: string, re: pattern): set of string
  Returns all occurrences of re in s (or an empty empty set if none).
- find\_last(s: string, re: pattern): string
  Returns the last occurrence of re in s. If not found, returns an empty string.
  Note that this function returns the match that starts at the largest index in the string, which is not necessarily the longest match. For example, a pattern of /.\*/ will return the final character in the string.
- hexdump(data: string): string
  Returns a hex dump for data. The hex dump renders 16 bytes per line, with
  hex on the left and ASCII (where printable) on the right. Based on Netdude's
  hex editor code.
- find\_entropy(data: string): entropy\_test\_result
  Performs an entropy test on data. The result is a record with the following
  fields:
  - entropy: The information density expressed as a number of bits per character.
  - chi\_square: The  $\chi^2$  test value expressed as an absolute number and a percentage which indicates how frequently a truly random sequence would exceed the value calculated, i.e., the degree to which the sequence tested is suspected of being non-random.
  - mean: The arithmetic mean of all the bytes. If the data are close to random, it should be around 127.5. If the percentage is greater than 99% or less than 1%, the sequence is almost certainly not random. If the percentage is between 99% and 95% or between 1% and 5%, the sequence is suspect. Percentages between 90% and 95% and 5% and 10% indicate the sequence is "almost suspect".
  - monte\_carlo\_pi: Each successive sequence of six bytes is used as 24-bit x and y co-ordinates within a square. If the distance of the randomly-generated point is less than the radius of a circle inscribed within the square, the six-byte sequence is considered a "hit." The percentage of hits can be used to calculate the value of  $\pi$ . For very large streams the value will approach the correct value of  $\pi$  if the sequence is close to random.
- serial\_correlation: This quantity measures the extent to which each byte
  in the file depends upon the previous byte. For random sequences this value
  will be close to zero. Also known as autocorrelation.
- entropy\_test\_init(index: any): bool
  Initializes data structures for incremental entropy calculation. The index ar-

- gument is an arbitrary unique value per distinct computation. Returns true on success. See entropy\_test\_add and entropy\_test\_finish.
- entropy\_test\_add(index: any, data: string): bool
   Add data to the incremental entropy calculation identified by index. Returns true on success.
- entropy\_test\_finish(index: any): entropy\_test\_result Finalizes the incremental entropy calculation identified by index. When all data has been added, this function returns the result record which is described above in find\_entropy.

### **Network Type Processing**

- mask\_addr(a: addr, top\_bits\_to\_keep: count): subnet
  Returns the address a masked down to the number of upper bits indicated by
  top\_bits\_to\_keep, which must be greater than 0 and less than 33. For example,
  mask\_addr(1.2.3.4, 18) returns 1.2.0.0, and mask\_addr(1.2.255.4, 18)
  returns 1.2.192.0.
- remask\_addr(a1: addr, a2: addr, top\_bits\_from\_a1: count): count
  Takes some top bits (e.g., subnet address) from a1 and the other bits (intrasubnet part) from a2 and merge them to get a new address. This is useful for
  anonymizing at subnet level while preserving serial scans.
- is\_tcp\_port(p: port): bool Checks whether p is a TCP port.
- is\_udp\_port(p: port): bool Checks whether p is a UDP port.
- is\_icmp\_port(p: port): bool Checks whether p is an ICMP port.
- connection\_exists(id: conn\_id): bool
  Checks whether the connection identified by id is (still) active.
- lookup\_connection(id: conn\_id): connection Returns the connection record for id. If id does not point to an existing connection, the function returns a run-time error and returns a dummy value.
- unescape\_URI(URI: string): string Unescapes all characters in URI, i.e., decodes every %xx group.
- lookup\_location(a: addr): geo\_location Performs a geo-lookup of the IP address a. Returns city, region, and country. Needs libgeoip.
- lookup\_asn(a: addr): count Performs a AS number lookup of the IP address a. Needs libgeoip.
- x509\_verify(der\_cert: string, cert\_stack: vector of string, root\_certs: table[string] of string): count

  Verifies the X 509 certificate in DER format given by der cert. T

Verifies the X.509 certificate in DER format given by der\_cert. The argument cert\_stack specifies a certificate chain to validate against, with index

0 typically being the root CA. Bro uses the Mozilla root CA list by default; root\_certs extends that list with additional root certificates.

• x509\_err2str(err\_num: count): string Converts the X.509 certificate verification error code err\_num into a string rep• interval\_to\_double(i: interval): double resentation.

#### Conversion

• cat(...): string

Returns the concatenation of the string representation of its arguments, which can be of any type. For example, cat("foo", 3, T) returns "foo3T".

- cat\_sep(sep: string, default: string, ...): string Similar to cat, but places sep between each given argument. If any of the variable arguments is an empty string it is replaced by default instead.
- fmt(...): string

Produces a formatted string. The first argument is the format string and specifies how subsequent arguments are converted for output. It is composed of zero or more directives: ordinary characters (not %), which are copied unchanged to the output, and conversion specifications, each of which fetches zero or more subsequent arguments. Conversion specifications begin with % and the arguments must properly correspond to the specifier. After the %, the following characters may appear in sequence:

% Literal % Left-align field The field width (< 128)[0-9]+Precision of floating point specifiers [efg] (< 128) Escape NUL bytes, i.e., replace 0 with \0 Format specifier [DTdxsefg] [DT] ISO timestamp with microsecond precision Signed/Unsigned integer (using C-style %11d/%11u for d int/count) Unsigned hexadecimal (using C-style %11x); dresses/ports are converted to host-byte order Escaped string [efg] Double

Given no arguments, fmt returns an empty string. Given a non-string first argument, fmt returns the concatenation of all its arguments, per cat. Finally, given the wrong number of additional arguments for the given format specifier, fmt generates a run-time error.

- to\_int(s: string): int Converts a string into a (signed) integer.
- int\_to\_count(n: int): count Converts a positive integer into a count or returns 0 if n < 0.
- double\_to\_count(d: double): count

Converts a positive double into a count or returns 0 if d < 0.0.

- to\_count(s: string): count Converts a string into a count.
- Converts an interval time span into a double.
- double to interval(d: double): interval Converts a double into an interval.
- time\_to\_double(t: time): double Converts a time value into a double.
- double\_to\_time(d: double): time Converts a double into a time value.
- double\_to\_time(d: double): time Converts a double into a time value.
- port\_to\_count(p: port): count Returns the port number of p as count.
- count\_to\_port(num: count, t: transport\_proto): port Creates a port with number num and transport protocol t.
- to\_port(s: string): port Converts a string into a port.
- addr\_to\_count(a: addr): count Converts an IP address into a 32-bit unsigned integer.
- count\_to\_v4\_addr(ip: count): addr Converts an unsigned integer into an IP address.
- to\_addr(ip: string): addr Converts a string into an IP address.
- raw\_bytes\_to\_v4\_addr(b: string): addr Converts a string of bytes into an IP address. It interprets the first 4 bytes of b as an IPv4 address in network order.
- ptr\_name\_to\_addr(s: string): addr Converts a reverse pointer name to an address, e.g., 1.0.168.192.in-addr.arpa to 192.168.0.1.
- addr\_to\_ptr\_name(a: addr): string Converts an IP address to a reverse pointer name, e.g., 192.168.0.1 to 1.0.168.192.in-addr.arpa.
- parse\_dotted\_addr(s: string): addr Converts a decimal dotted IP address in a string to an address type.
- bytestring\_to\_hexstr(bytestring: string): string Converts a string of bytes into its hexadecimal representation, e.g., "04" to "3034".
- decode\_base64(s: string): string Decodes the Base64-encoded string s.

- decode\_base64\_custom(s: string, a: string): string Decodes the Base64-encoded string s with alphabet a.
- uuid\_to\_string(uuid: string): string Converts a bytes representation of a UUID to its string form, e.g., to 550e8400-e29b-41d4-a716-446655440000.
- merge\_pattern(p1: pattern, p2: pattern): pattern Merges and compiles the regular expressions p1 and p2 at initialization time (e.g., in the event bro\_init()).
- convert\_for\_pattern(s: string): string
  Escapes s so that it is a valid pattern and can be used with
  the string\_to\_pattern. Concretly, any character from the set
  ^\$-:"\/|\*+?.(){}[] is prefixed with \.
- string\_to\_pattern(s: string, convert: bool): pattern Converts s into a pattern. If convert is true, s is first passed through the function convert\_for\_pattern to escape special characters of patterns.
- NFS3::mode2string(mode: count): string
  Convert UNIX file permissions given by mode to a string representation of the
  form rw[xsS]rw[xsS]rw[xtT].
